## 1. INTRODUCTION

Green NCAP is an initiative established in 2018 to provide consumers with comprehensive, holistic and independent information regarding the environmental impact of new cars. Legislation in this area has become very much more rigorous, partly in response to revelations of some manufacturers 'cheating' emissions tests by utilising different software (so-called 'engine maps') when the tests are conducted to those used in normal driving. However, even without resorting to such measures, vehicle manufacturers are able, perfectly legally, to utilise those areas of the engine map which are not explored in the tests to enhance real-world performance or emissions abatement. Green NCAP conducts a wide variety of tests, based on those used in legislation but with 'extended boundaries', to explore more completely the engine speed/load range. In so doing, it aims to promote clean, efficient functioning of the engine and exhaust after-treatment at all times.

Protection of the environment is a broad topic and is divided into three areas in Green NCAP's assessments. The immediate environment, such as those in cities where people work and live, is perhaps most immediately affected by pollutant emissions: those by-products of the combustion process which are harmful to health. This is addressed by the Clean Air Index. The global environment is affected by the emission of gases which prevent heat from escaping from the planet, and which are responsible for the relentless rise in average temperatures which has been taking place for decades. This is addressed by the Greenhouse Gas Index. And, on top of this, the natural resources which need to be put into a vehicle to make it move – directly, in the form of petrol or diesel, or indirectly in the case of fossil-fuel derived electricity – are finite and should be used as sparingly as possible, for the benefit of the planet and for the consumer who pays for them. This area is addressed by the Energy Efficiency Index.

This document details the way in which the results of Green NCAP's tests are scored and how those scores are used to calculate the star rating.

## 2. THE STAR RATING

The star rating is derived from the three indexes: Clean Air, Energy Efficiency and Greenhouse Gas. The methods used to calculate those indexes will be described in the sections to follow. For now, it is sufficient to know that index is a score, out of a maximum of ten, for the performance of the vehicle in each of those three areas of assessment. Ten points represents the maximum points that are available in each of the pillars.

#### 2.1. Weighted average

The three indexes, each to one decimal place, are used to calculate a weighted average, known as the 'overall index'. Currently the weighting is as follows:

Table 1 Index Weightings					
Index Clean Air Energy Efficiency Greenhouse Gas					
Weight	0.333	0.333	0.333		

In other words, all three indexes are given equal weighting and the overall index is, for now, a simple average of the three. The weighted average is rounded *down* to the nearest one decimal place e.g. indexes for Clean Air, Energy Efficiency and Greenhouse Gases of 4.9, 5.1 and 4.9 respectively yields a weighted average of 4.967. This is rounded to 4.9, *not* to 5.0, as the threshold of 4.9 has been met and exceeded, while the threshold of 5.0 has not.

The overall index is then compared to a table of thresholds, at which the car is deemed to have met the requirements of certain star, or half-star, ratings. The table is:

Tuble 2 Otal Rating Thresholds			
Stars	Threshold		
***	9.0		
	8.0		
	7.0		
****	6.0		
	5.0		
****	4.0		
***	3.0		
	2.0		
<b>*</b> * * * *	1.0		
	0.0		

#### **Table 2 Star Rating Thresholds**

So a car with an overall index of 5.2 is rated as a three-star vehicle; another with an overall index of 2.8 is considered a one-and-a-half-star vehicle.

## 3. THE INDEXES

#### 3.1. The Clean Air Index

#### 3.2. The Pollutants

The pollutants considered in the calculation of the Clean Air Index are as follows:

#### **Table 3 Pollutant Emissions**

Pollutant	Abbreviation
Non-methane hydrocarbons	NMHC
Oxides of nitrogen	NOx
Nitrogen dioxide	NO <sub>2</sub>
Ammonia	NH <sub>3</sub>
Carbon Monoxide	СО
Particulate Mass	PM
Particulate Number	PN

#### 1.1.1. The Tests

The tests employed are as follows:

Table 4 Green NCAP Tests				
	Test			
	WLTC – cold start (WLTC-cold) (14°C)			
Laboratory	WLTC – warm start (WLTC – warm)			
Tests	WLTC – cold ambient temp (WLTC-CAT) (-7°C)			
	Motorway test (BAB130)			
	PEMS (cold Engine, 2 times)			
Real Driving	PEMS (Short urban trip, 2 times)			
Emissions	PEMS (Eco/light)			
EIIIISSIOIIS	PEMS (Heavy load)			
	PEMS (Congestion)			

WLTC: World-harmonised Light-duty Test Cycle

PEMS: Portable Emissions Measuring System

The procedures used for each of the tests is described in detail in other Green NCAP procedures

#### 1.1.2. Limit Values

For each test, the scoring of each relevant pollutant is based on the final bag measurement of that pollutant. For each, there is a lower emissions (i.e. high-performance) limit, below which maximum points are scored, and an upper emissions (i.e. low-performance) limit above which no, or negative, points are scored. There is also a 'gross exceedence' limit for each pollutant (1.5 times upper limit, except PN: one order of magnitude. Different limit values apply to different tests, as follows:

Pollutant	Lower Limit	Upper Limit	Gross Exceedence		
NMHC (mg/km)	0.0	58	87		
NO <sub>x</sub> (mg/km)	0.0	60	90		
NO <sub>2</sub> (mg/km)	0.0	20	30		
NH₃ (mg/km)	0.0	10	15		
CO (mg/km)	0.0	500	750		
PM (mg/km)	0.0	4.5	6.75		
PN	0.0	6 x 10 <sup>11</sup>	6 x 10 <sup>12</sup>		

#### Table 5 Clean Air Limit Values (1): Applies to: WLTC-cold, WLTC-warm, BAB130

## Table 6 Clean Air Limit Values (2): Applies to: PEMS+ cold, PEMS light load, PEMS congestion, WLTC-CAT, PEMS heavy load, PEMS 8km

Pollutant	Lower Limit	Upper Limit	Gross Exceedence
NMHC (mg/km) <sup>1</sup>	not tested		
NO <sub>x</sub> (mg/km)	0.0	79	119
NO <sub>2</sub> (mg/km) <sup>1</sup>	0.0	26	40
NH₃ (mg/km) ¹	0.0	13	20
CO (mg/km)	0.0	660	990
PM (mg/km) <sup>1</sup>	0.0	6	9
PN	0.0	7.92 x 10 <sup>11</sup>	1.0 x 10 <sup>12</sup>

(a conformity factor of 1.32 is applied for PEMS compared to laboratory tests)

<sup>1</sup>Not relevant to PEMS tests

For the PEMS congestion test, only NOx is measured and the limits are as follows:

Table 7 Clean Air Limit Values (3)				
Pollutant Average Maximum				
NO <sub>x</sub> (mg/s) 0.5 1.0				

### Table 7 Clean Air Limit Values (3)

#### 3.2.1. The Scoring Principle

Within each test, each pollutant can score a maximum number of points for values of emissions which are at or below the lower limit, down to zero at the upper limit, and can be negative for values beyond the upper limit. Particulate number is calculated on a logarithmic scale while all other pollutants are scored linearly.

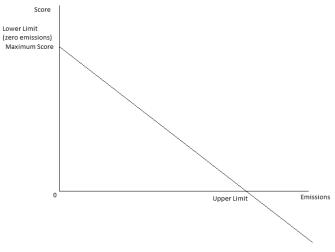

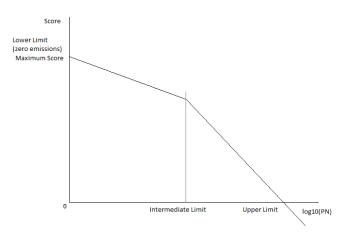

Figure 1 Linear Scoring Method

For particulate number, a logarithmic scale is used

#### Figure 2 Logarithmic Scoring for Particulate Number

The maximum score per pollutant varies by test.

Pollutant	all WLTC and BAB130	PEMS+ cold	PEMS light	PEMS heavy	PEMS 8km <sup>2</sup>	PEMS congestion
NMHC (mg/km)	2	-	-	-	-	-
NO <sub>x</sub> (mg/km <sup>1</sup> )	3	2	2.25	3.6	1.125	2
NO <sub>2</sub> (mg/km)	0	-	-	-	-	-
NH₃ (mg/km)	1	-	-	-	-	-
CO (mg/km)	1	1	0.5	0.8	0.25	-
PM (mg/km)	0	-	-	-	-	-
PN	3	2	2.25	3.6	1.125	-
Maximum Points	10	5	5	8	2.5	2

#### Table 8 Maximum Scores per Test (Clean Air)

<sup>1</sup> mg/s for the PEMS Congestion test

<sup>2</sup> carried out twice

The total score per test is the sum of the scores for the individual pollutants, with the following notes:

- Capping. If any pollutant, with the exception of NH<sub>3</sub>, exceeds its gross exceedence value, the score for that test is set to zero, regardless of the performance of the other pollutants. Tests are not capped in this way for NH<sub>3</sub> which is unregulated by legislation.
- If the sum of the scores of individual pollutants is less than zero, the score for the test is set to zero i.e. the minimum score for tests in the Clean Air Index is zero.
- In the PEMS Congestion test, a score of 1 point is awarded if the average NO<sub>x</sub> emission rate is less than the prescribed maximum, and an additional 1 point is awarded if the maximum NO<sub>x</sub> emission rate is lower than its prescribed maximum.
- Scoring for PEMS light: if the value of any pollutant is less than its value in the PEMS+ cold test, the maximum score is awarded for that pollutant. If the value of the pollutant is above the upper limit, no points are scored. For values between that in the PEMS+ cold test and the upper limit, a sliding scale is used.
- Scoring for PEMS heavy: if the score for that pollutant in the PEMS+ cold test was zero, then
  no points can be scored for that pollutant in the PEMS heavy test. Otherwise, if the value of
  the pollutant emissions is less than the upper limit of the PEMS+ cold test, maximum points are
  scored for that pollutant.
- Scoring for PEMS 8km: the test is done twice. For both tests, the following applies: if the score
  for a pollutant was zero in the PEMS+ cold test, then no points can be scored for that pollutant
  in the PEMS heavy test. If the value of the pollutant emissions in *either* of the PEMS 8km tests

exceeds the (extended) gross exceedence limit, then the score for that pollutant is zero. Otherwise, the score is calculated on a sliding scale between (maximum points at zero to zero points at the gross exceedence limit.

#### 3.2.2. Total Score and Calculation of the Index

The points from each of the tests are summed and the result is divided by the maximum points that can be achieved in the Clean Air assessment (currently 40). The result is rounded down to one decimal place and multiplied by ten.

#### 3.3. The Greenhouse Gas Index

#### 3.3.1. The Greenhouse Gases

The gases considered in the calculation of the Greenhouse Gas Index are as follows:

#### Table 9 Greenhouse Gases

Greenhouse Gas	Abbreviation
Carbon dioxide	CO <sub>2</sub>
Nitrous oxide	N <sub>2</sub> O
Methane	CH <sub>4</sub>

#### 3.3.2. The Tests

The tests used are the same as those used for the Clean Air Index. See Section 2.1.4

#### 3.3.3. Limit Values

The following limit values apply:

#### Table 10 Greenhouse Gas Limit Values (1): Applies to: WLTC-cold, WLTC-warm, BAB130

Pollutant	Lower Limit	Upper Limit
CO <sub>2</sub> (g/km)	0.0	175
N <sub>2</sub> O (mg/km)	0.0	6.2
CH4 (mg/km)	0.0	32

 Table 11 Greenhouse Gas Limit Values (2): Applies to: PEMS+ cold, PEMS light load, PEMS

 congestion, WLTC-CAT, PEMS heavy load, PEMS 8km

(a conformity factor of 1.5 is applied for PEMS compared to laboratory tests)

Pollutant	Lower Limit	Upper Limit
CO <sub>2</sub> (g/km)	0.0	262.5
N <sub>2</sub> O (mg/km)	0.0	9.3
CH <sub>4</sub> (mg/km)	0.0	48

#### Table 12 Greenhouse Gas Limit Values (3): Applies to: WLTC-CAT

(a conformity factor of 1.6 is applied for WLTC-CAT to other laboratory tests)

Pollutant	Lower Limit	Upper Limit
CO <sub>2</sub> (g/km)	0.0	175
N <sub>2</sub> O (mg/km)	0.0	9.92
CH <sub>4</sub> (mg/km)	0.0	51.2

#### 3.3.4. The Scoring Principle

Points are scored in the same way as for pollutants in the Clean Air Index. Only a linear scale is used in this case. The maximum score per gas varies by test.

Greenhouse Gas	all WLTC and BAB130	All PEMS tests <sup>1</sup>
CO <sub>2</sub>	1	0
N <sub>2</sub> O	2	0
CH <sub>4</sub>	4	0
Maximum Points	7	0

#### Table 13 Greenhouse Gas Maximum Scores per Test

<sup>1</sup> Greenhouse gases measured in PEMS tests are not currently used for scoring

#### 3.3.5. Total Score and Calculation of the Index

The points from each of the tests are summed and the result is divided by the maximum points that can be achieved in the Greenhouse Gas assessment (currently 28) and multiplied by ten. The result is rounded down to one decimal place.

#### 3.4. The Energy Efficiency Index

#### 3.4.1. What is measured?

In simple terms, energy consumption is measured. The precise way in which this is done varies by fuel/energy type and details are contained in the individual test procedures. In summary, units of consumption are as follows:

Table 14 Energy Effici	ency Units of Consumption

Energy Source	Units of Consumption
Petrol, Diesel	I / 100km
Battery Electric	kWh / 100km
CNG, Hydrogen Fuel Cell	kg / 100km

#### 3.4.2. The Tests

Energy Efficiency is calculated on the basis of results in the laboratory tests defined previously. (PEMS test are not suitable). See Section 2.1.2.

#### 3.4.3. Energy Equivalent

To be able to compare energy efficiency between the different power sources, the consumption is converted into an equivalent energy. Conversion factors are based on the known calorific content of the fuel types. In the case of battery electric vehicles, no conversion is needed as the units of consumption are already in SI units.

Energy Source	Conversion Factor to kWh / 100km
Petrol (RON95, E10)	8.64
Diesel B7	9.79
CNG (high Methane)	13.89
Hydrogen	33.61
Electricity	1.00

#### **Table 15 Energy Conversion Factors**

#### 3.4.4. The Scoring Principle

A linear sliding scale is used for scoring, as described in Section 2.1.4. The following limits and scores are used for all tests and for all engine types/energy sources:

Table 15 Energy Efficiency Limits			
Lower Limit kWh / 100km	Upper Limit kWh / 100km	Maximum Score (≤ Lower Limit)	Score at Upper Limit
30	90	10	0

#### Table 15 Energy Efficiency Limits

Notes:

• Energy consumption beyond the upper limit leads to negative scores. The minimum score per test is limited to zero.

#### 3.4.5. Calculation of the Energy Efficiency Index

The scores for the four lab tests are summed (taking into account that the score for any individual test may be negative). The total is divided by the maximum points available in this part of the assessment (currently 40) and multiplied by ten. The result is rounded down to one decimal place.

#### 3.5. VISUALISATION OF RESULTS

Green NCAP's website presents the results of the tests to consumers in a way that is easy to comprehend. A colour scheme is adopted, representing different levels of performance. The logic for choosing the colour is based on the score as a proportion of the maximum that could have been scored. This applies to the individual pollutants and gases in each test, to the energy efficiency in each test, and also to indicators of overall performance, such as all laboratory tests combined for example. The colouring logic is as follows:

Colour	Description	Logic (x = Score/Max Score)
Green	Good	x >=0.90
Yellow	Adequate	0.60 <= x < 0.90
Orange	Marginal	0.30 <= x < 0.60
Brown	Weak	0.00 < x < 0.30
Red	Poor	x <= 0.00

#### Table 16 Logic for Colouring in Visualisation

## 4. APPENDIX 1

#### Rationale behind method and limit values

Section	Rationale
1.1	Currently, the average index takes equal weights from Clean Air, Energy Efficiency and Greenhouse Gases. This makes all three equally important in terms of their influence on the star rating, reflecting equal weighting for public health, consumer spending and global warming, respectively. In Greenhouse Gases, CO <sub>2</sub> is one of the main constituents upon which the index is scored. In Energy Efficiency, CO <sub>2</sub> is used as a proxy for fuel consumption for combustion-engined cars. This weighting will be reviewed in the future. Bi-fuel vehicles, e.g. CNG/petrol, are also undergo a limited amount of additional tests in petrol mode (WLTC-warm, PEMS+ and BAB Motorway). When for a specific component the ratio between primary and secondary fuel exceeds 1.5 a modifier of 50% is applied. If the emitted amount of a component in secondary fuel mode is doubled, but still below the limit, no modifier shall be applied. [PHEV's are tested in charge depletion as well as charge sustaining mode. Results will be combined]
2.1.1	These are the pollutant emissions which are considered the most important ones which can be measured. Particle number (PN) is based on measurement of PN23 particles. Research has been done to study the correlation between this number and the number of sub-10nm (PN10) particles. The measurement method may be refined to PN10 in time.
2.1.2	Details of the test methods are given in other procedures. Laboratory tests (WLTC and BAB130) are based on established test procedures. However, Green NCAP extends the boundary conditions to include different start temperatures and different ambient temperatures. In the same vein, the on-road tests are performed in a variety of load conditions – light load, heavy load etc – to better simulate real-world car use.
2.1.3	The same limit values are used for all fuel and types and energy sources, to makes the assessment and comparison of results technology-neutral. The lower limit values are always set to zero emissions. In other words, only zero tailpipe emissions are given maximum score for the Clean Air Index. The upper limits for laboratory tests are based on the lowest value of diesel and petrol Euro 6d limit values. As this is the allowable legal limit, no points are scored for the pollutant at these values or beyond. In the THC limit CH4 was taken out and shifted to 'Greenhouse Gas', resulting in a limit NMHC. The gross exceedence limit represents the point at which the score for the entire test is capped to zero i.e. if any constituent pollutant reaches or exceeds this value, no points are scored in that test. The only exception is ammonia, NH <sub>3</sub> , which is not regulated by legislation. For NH3 the limit value is derived from the requirements for HDVs (UN-R49)
	A conformity factor of 1.32 (recommended by JRC) is applied for the upper limits of PEMS tests compared to the lab tests as measurement repeatability is less precise.
2.1.4	A linear scale is used for scoring of all pollutants except PN, between a maximum number of points for zero emissions, to zero points at the upper limit. Beyond this limit, scoring becomes negative, following the same slope. This, a car which performs well for one pollutant will have its score in that test decreased if another pollutant is above the upper limit. This encourages good performance all-round and discourages optimisation of one at the expense of another pollutant.
	For PN, a logarithmic scale is used, decreasing from a maximum at zero to $2/3 \times$ Maximum at a value of $10^8$ (i.e. a $\log_{10}$ value of 8) and, from there, to a score of zero at 6 x $10^{11}$ , the Euro 6d limit. Beyond 6 x $10^{11}$ , the score continues to follow the line, becoming negative.

	The maximum score per pollutant reflects their relative harmful effects, and varies by the importance of the test.
2.2.1	These are the three most significant greenhouse gases emitted by vehicles. CO <sub>2</sub> is emitted in vastly greater quantities than N <sub>2</sub> O or CH <sub>4</sub> . However, the latter have a more powerful greenhouse gas effect, and last longer in the atmosphere.
2.2.3	CH <sub>4</sub> and N <sub>2</sub> O are not regulated in Europe. The upper limit value for N2O is taken from US legislation. CH <sub>4</sub> upper threshold corresponds to the subtraction of THC_Euro6 by the NMHC_Euro6 limits The CO <sub>2</sub> limit is derived from the fleet average of cars tested in ADACs Ecotest program.
	There are no gross exceedance values for the Greenhouse Gas Index, and no capping of tests.
2.2.4	The maximum scores reflect the relative importance of the greenhouse gases. Only a linear scale is used in this index. Measurements in PEMS tests are not yet repeatable enough to be used in the calculation of this index, so their maximum scores are zero (i.e. they do not currently contribute to the Greenhouse Gas Index)
2.3.3	Standard test fuels are used, with known calorific properties.
2.3.4	A linear scale is used. However, for energy efficiency, the lower limit (maximum points) is not zero, as all cars need to use <i>some</i> energy to move. The lower limit in this case is 30 kWh/100km; the upper limit, at which no points are scored, is 90 kWh/100km. These values are chosen to reflect the typical range of energy consumptions seen in modern vehicles and to give some resolution in results.
	The minimum score per test is zero (i.e. a test cannot have a negative score).
3	Colours are based on scores as a proportion of the maximum available for that constituent in that test. With lower limits of zero (i.e. any tailpipe emission leads to a drop in score), a band of 10 percent is allowed to define 'good' performance. 'Poor' performance is defined as a value of emission at or beyond the prescribed upper limit. The bands representing other levels of performance are split equally between in the range 0 = 90 percent.
